

Periodic Trends

Atomic Radius, Ionization Energy, Electron Affinity, and Electronegativity

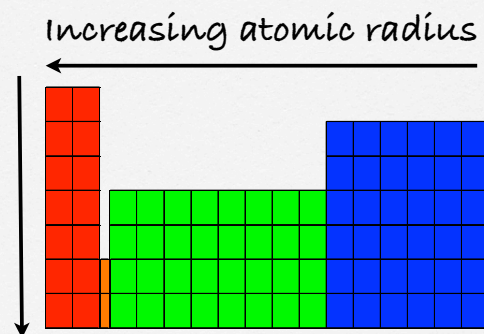

Atomic Radius

- Half the distance between nuclei of 2 atoms of the same element
- Measured in picometers ($1\text{pm} = 10^{-12}\text{m}$)

The Trend:

- 1) Decreases from left to right across a period
☑ stronger pull from increasing # of protons
- 2) Increases from top to bottom in a group
☑ Each energy level places electrons further from the nuclear pull

Follow the arrows

Decreasing atomic size

Effective Nuclear Charge (ENC) exerts a pull on the valence electrons

$$\text{ENC} = \# \text{ of protons} - \# \text{ of core electrons}$$

Decreasing atomic radius

Li (ENC = 1) Be (ENC = 2) B (ENC = 3)

Trends in Atomic Radius (Å) show rule

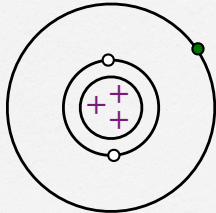

1A	2A	3A	4A	5A	6A	7A	8A
H 0.37							He 0.5
Li 1.52	Be 1.11	B 0.88	C 0.77	N 0.70	O 0.66	F 0.64	Ne 0.70
Na 1.86	Mg 1.60	Al 1.43	Si 1.17	P 1.10	S 1.04	Cl 0.99	Ar 0.94
K 2.31	Ca 1.97	Ga 1.22	Ge 1.22	As 1.21	Se 1.17	Br 1.14	Kr 1.09
Rb 2.44	Sr 2.15	In 1.62	Sn 1.40	Sb 1.41	Te 1.37	I 1.33	Xe 1.30
Cs 2.62	Ba 2.17	Tl 1.71	Pb 1.75	Bi 1.46	Po 1.5	At 1.4	Rn 1.4

Ionic Radius

- Positive Ion (Cation):
 - Drop one energy level, therefore decreasing the radius
- Negative Ion (anion):
 - radius increases due to electron-electron repulsion

Cations: One less energy level

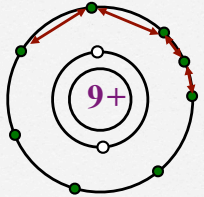

lithium (Li)

lithium ion (Li⁺)

Anions: Electron-Electron Repulsion

Electron-Electron Repulsion

Therefore, Fluorine (F)

is smaller than its ion (F⁻)

Ionization Energy

Amount of energy required to remove an electron from the atom or ion in the gaseous state

The Trend:

- 1) Decreases as you move down a group
 further from nucleus, therefore less energy to pull it away
- 2) Increases from left to right across a period
 higher ENC as we add more protons

Second Ionization Energy

- it's always harder to remove a second electron because you decrease AR as you remove the first electron = less electron-electron repulsion

Electron Affinity

- The energy change from a gaseous atom accepting an electron
- Increases as we go across a period (L to R) and decreases as we go down a group.
- Why?
 - Inversely related to atomic radius
 - Smaller radii allow the positive nucleus to attract nearby electrons

Electronegativity

- Pauling's way of combining ionization energies and electron affinity
- Increases across a period (L to R)
- Decreases down a group
- Why?
 - Again, AR. Smaller atoms have more pull on electrons = electronegative (top right: Fluorine, bottom left: Francium)

Summary

When AR Increases (down a group)

- Electrons are far from the nucleus, therefore ionization energy is LOW
- Electron affinity is also LOW, because the nuclear pull for electrons is well shielded (by distance and other electrons from lower levels)
- Electronegativity is LOW b/c the above 2 are low

Summary

When AR Decreases (across a period, L-R)

- Electrons have stronger pull from the nucleus, therefore ionization energy is HIGH
- Electron affinity is HIGH because there is little shielding from electrons – the nuclear pull is stronger
- Electronegativity is HIGH because the above 2 are HIGH
